

The use of GIS tools for analyzing eye-movement data

Tomasz Opach Jan Ketil Rød

some facts

In recent years an eye-tracking approach has become a common technique for collecting data in empirical user studies in cartography

Its popularity within this discipline has grown out of two basic convictions that it provides information about **user's visual behavior** and it does so in an **unobtrusive manner**

As a matter of fact these are advantages which distinguish eye-tracking from other empirical techniques known from usability studies

challenges and needs

Eye-tracking produces an **enormous amount of data** which is challenging for the analysis and which to some extent impedes the use of this technique

In order to analyze eye-movement data **we might use dedicated software packages**, however, they sometimes do not offer the functionality that one needs

Then, common **GIS applications might be helpful** for the analysis of the output from eye-trackers which usually can be exported as fixation points data

what do GIS tools offer?

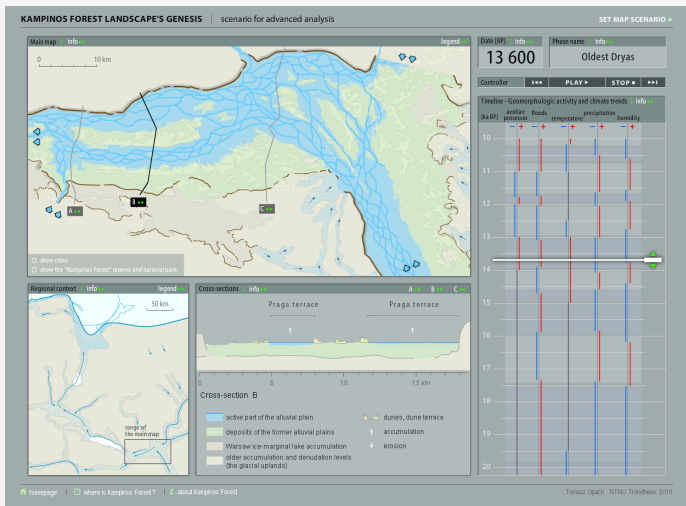

GIS tools may provide users with new insights which are difficult to derive while using default eye-tracking software

Fixation points* can be **exported to any GIS application**

**points to which a human has directed his/her visual attention and gathered as an output from eye-tracker*

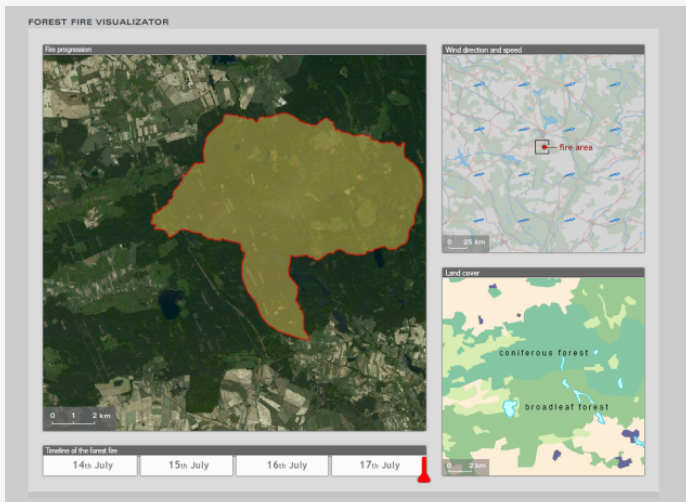

Since we may consider the screen as defining a Cartesian coordinate system, these fixation points are spatial data and of course we could use a tool-rich **GIS to visualize and analyze eye-movement data**

where were they used?

Project 1

Evaluation of the multi-component and multi-scenario animated map of the Kampinos Forest's landscape genesis

Project 2

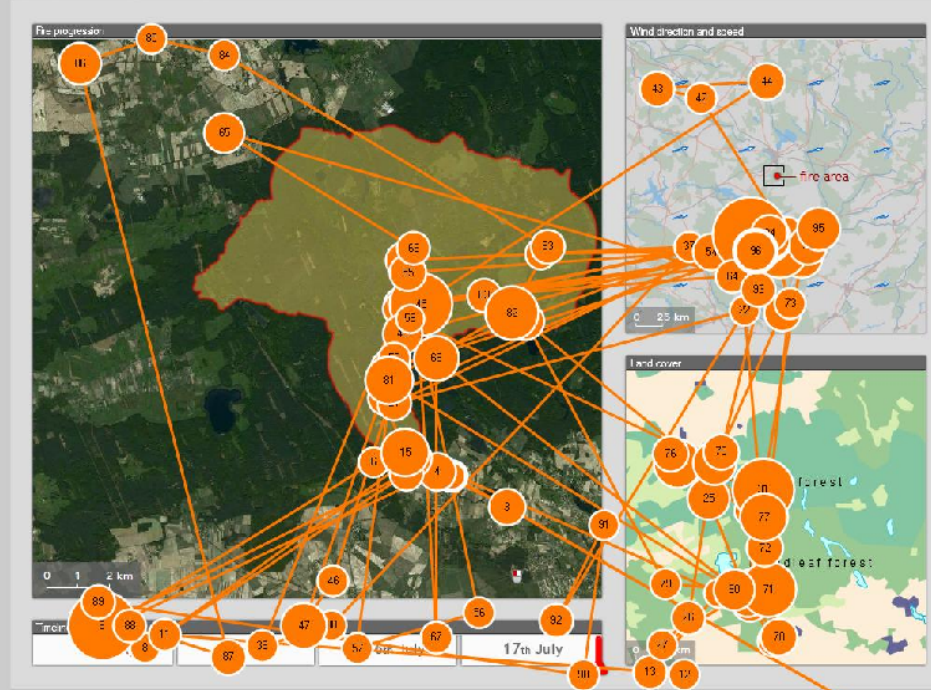

How do people view multi-component animated maps?

fixation filter threshold

GIS applications may facilitate optimization of the fixation filter threshold

Fixation points set after filtering (aggregating) can be easily compared with the raw data so users are able to evaluate whether raw fixation points have been “aggregated” in accordance with their observations or expectations

changes over time

Users may want to view fixations and saccades in a form of the space-time-cube for easier analysis of eye movement data

Traditional approaches conceal space-time variation due to aggregation. Space-time-cube visualization facilitates the user to discover patterns

Even if the 3D visualization of eye-movement data is not enough for revealing patterns across participants it can help to drive the research into the appropriate direction and to formulate further hypotheses

space-time cube in GIS

When using GIS applications **users may easily customize space-time cube settings**, for instance, both fixation points and saccades can be symbolized depending on their temporal attributes

Furthermore **blocks built on the basis of the area-of-interest zones** can be additionally visualized in the scene to support visual analysis

Set map scenario

General

Description of the scenario

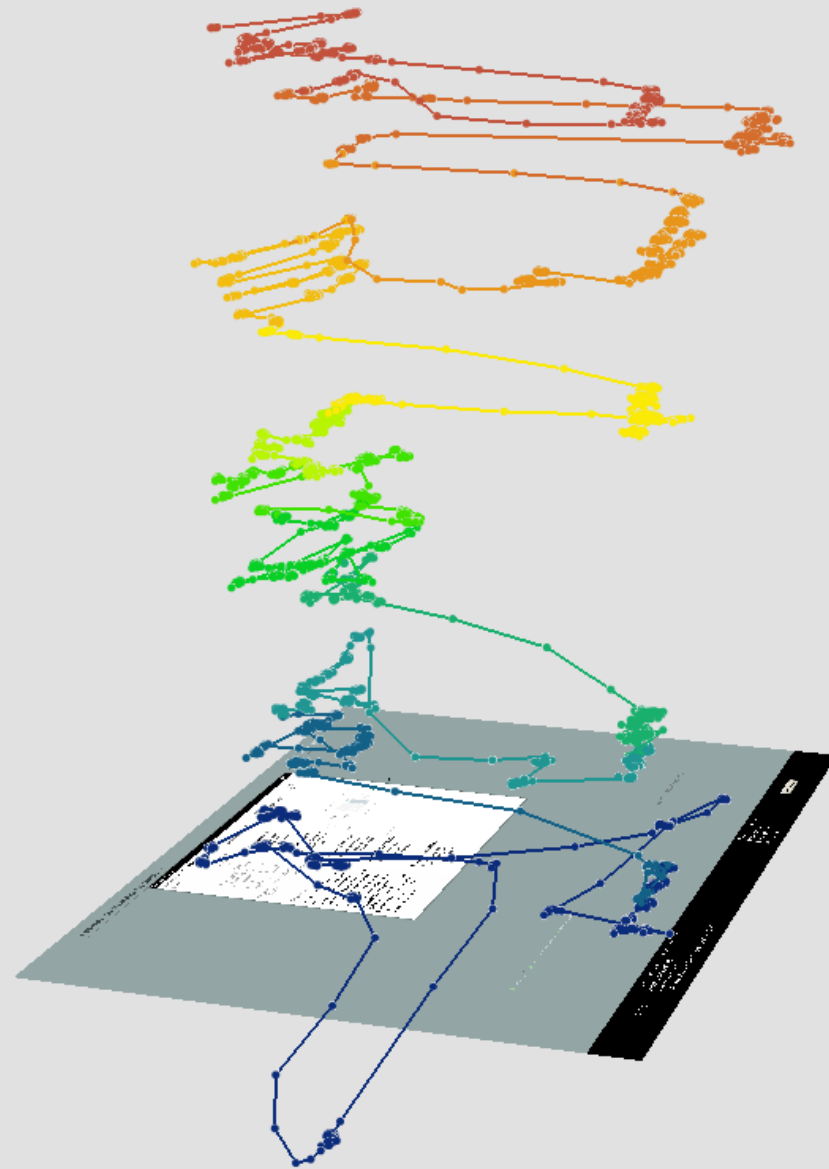

Scenario description: The map shows the forest landscape of Kampinos National Park. The map is divided into several zones, each with a different color. The zones are: 1. Forest (green), 2. Open land (yellow), 3. Water (blue), 4. Urban (red), 5. Agricultural (orange), 6. Industrial (purple), 7. Other (grey). The map also shows the boundaries of the park and the surrounding areas. The map is a vector map, which means it can be zoomed in and out without losing quality. The map is also interactive, which means you can click on different elements to get more information. The map is a good tool for understanding the forest landscape of Kampinos National Park and for planning its future development.

TASK 3

Use the information from the diagrams. View the timeline and find the answer to the question. Answer with 'Yes', 'No', 'June', 'June', 'July', 'July', 'August', 'August', 'September', 'September', 'October', 'October', 'November', 'November', 'December', 'December'. Was the temperature trend positive or negative?

- 14,000 - 15,000 years BP; negative
- 4,000 - 13,000 years BP; positive
- 3,000 - 12,000 years BP; lack of data
- I don't know

End task 3

Home page | Where is Kampinos Forest? | About Kampinos

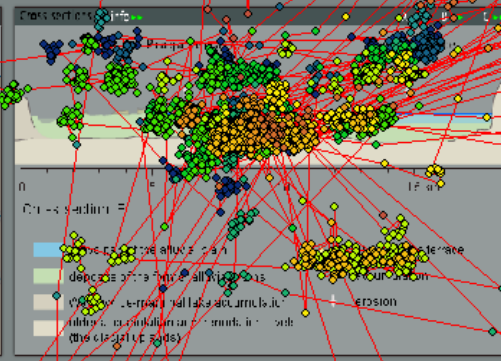

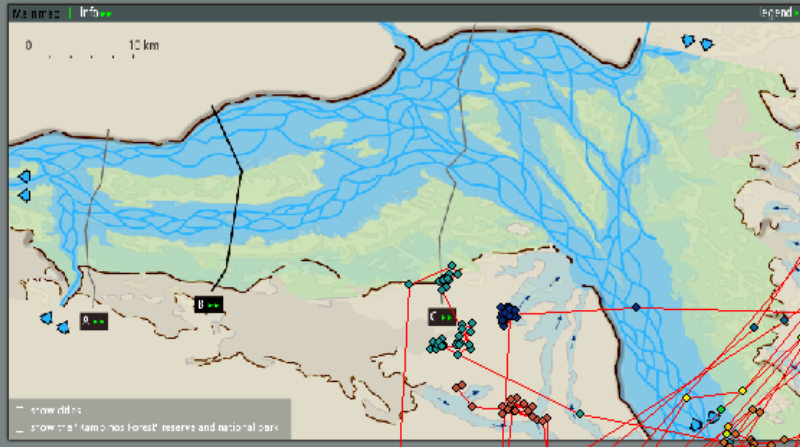

Tomasz Opach | IRTK | Tomasz Opach 2011

Use the legend to identify the different phases in the diagrams.
View the timeline and the data points for each phase.
→ Answer what the temperature trend was during the last
Was the temperature trend positive or negative?

- 20,000 - 15,000 years BP; negative
- 14,000 - 13,000 years BP; positive
- 3,000 - 12,000 years BP; lack of data
- I don't know

end task

TASK 3

Tomasz Opach, IITeD, Tomasz Opach, 2010

TASK 3

Use the information from the diagrams, view the film, and the cross-section to be displayed. Answer what were the 'Jungles' (Jungles) like? Was the temperature trend positive or negative?

- 20,000 - 15,000 years BP; negative
- 14,000 - 13,000 years BP; positive
- 13,000 - 12,000 years BP; lack of data
- I don't know

End task 3

conclusion

The examples are quite straightforward.

Nevertheless, they demonstrate the potential for GIS applied to eye-movement data analysis

For cartographers already acquainted with GIS tools it is quite easy to use such applications to handle eye movements data

There are of course much more possibilities of use, but their applicability depends on the goals which are addressed
